This paper is a revised version of "Business Dynamics Statistics of Coastal Counties: A Description of Differences in Coastal Areas Over Time" (CES 25-08) from January 2025. A copy of the original paper is available upon request.

CES 25-08R March 2025

The research program of the Center for Economic Studies (CES) produces a wide range of economic analyses to improve the statistical programs of the U.S. Census Bureau. Many of these analyses take the form of CES research papers. The papers have not undergone the review accorded Census Bureau publications and no endorsement should be inferred. Any opinions and conclusions expressed herein are those of the author(s) and do not necessarily represent the views of the U.S. Census Bureau. All results have been reviewed to ensure that no confidential information is disclosed. Republication in whole or part must be cleared with the authors.

Papers in the series are posted on www.census.gov/library/working-papers/series/ces-wp.html. For information about the series, contact Sean Wang, Editor, Discussion Papers, U.S. Census Bureau, Center for Economic Studies, 4600 Silver Hill Road, Washington, DC 20233, CES.Working.Papers@census.gov.

Abstract

The Business Dynamics Statistics of Coastal Counties (BDS-CC) is a new experimental data product extending the set of statistics published by the Business Dynamics Statistics (BDS) program to provide more detail on businesses operating in coastal regions of the United States. The BDS-CC provides annual measures of employment, the number of establishments and firms, job creation, job destruction, openings, and closings for businesses in Coastal Shoreline (CS), Coastal Non-Shoreline (CNS), and Non-Coastal (NC) counties. Counties are grouped into these categories based on definitions from the National Oceanic and Atmospheric Administration (NOAA). This product allows for comparisons across industries and coastal regions of the impact of natural disasters and other events that affect coastal areas. The BDS-CC series provides annual statistics for 1978 to 2022 for each of the coastal categories by firm size and firm age, initial firm size, establishment size and establishment age, initial establishment size, sector, 3-digit NAICS code, 4-digit NAICS code, urban/rural categories, and various coastal regions. Following a description of the data and methodology, we highlight some historical trends and analyses conducted using these data.

* Any opinions and conclusions expressed herein are those of the authors and do not represent the views of the U.S. Census Bureau. The Census Bureau has ensured appropriate access and use of confidential data and has reviewed these results for disclosure avoidance protection (Project No. 7508369: CBDRB-FY25-0042). We would like to thank Kimberly Blair, Sharad Chakravarthy, and Michael Lavarn, for their programming efforts and Cheryl Grim, Richard Beem, Sean Wang, Zach Kroff, Lorenz Ekerdt, and the LBD team for helpful suggestions and feedback. Special thanks to Mike Ratcliffe for developing the urban-rural county classifications. Corresponding author: Melissa Chow (melissa.c.chow@census.gov)

I. Introduction

Coastal areas are an important part of the United States from both a demographic and economic perspective. As of 2020, approximately 120 million people lived on the coast, representing 40% of the total U.S. population.[1] These areas accounted for 53% of national employment in 3.8 million establishments. Coastal counties play a large role in many sectors including transportation, tourism and recreation, and seafood farming. In 2020, areas along the coast accounted for 58% of employment in the Arts, Entertainment, and Recreation sector, which includes several subsectors related to tourism, and 49% of employment in the Transportation and Warehousing sector.[2] While coastal areas have been growing, with a 46% population increase since 1970 and an 80% employment increase from 1978 until 2020, coastal regions have also encountered new challenges.

Hurricanes and tropical storms have become more frequent and stronger in the last couple of decades. Since 2000, there have been a greater number of total hurricanes and Category 3+ hurricanes compared to averages from previous decades.[3] In addition to damages due to the immediate, direct hit of the hurricane, these natural disasters bring rain, strong winds, and flooding to areas that were not in the direct path of the hurricane, causing large amounts of physical and monetary damages. Between 2020 and 2022, there were 60 weather events with over $1 billion in damages.[4] Relative to 2000, there has also been an increase in the frequency of high tide flooding and sea level rises.[5] With increased concerns about the evolution of coastal areas and the growing population and business presence in coastal regions, it has become more important to understand the changes in firms, establishments, and employment in coastal areas that are impacted by storm damage and flooding.

In this paper, we introduce a new experimental data product, the Business Dynamics Statistics of Coastal Counties (BDS-CC), which documents differences in types of businesses operating in areas comprised of coastal counties and areas made up of inland counties. The BDS-CC is produced by the Center for Economic Studies (CES) at the U.S. Census Bureau and is an extension of the regularly released core Business Dynamics Statistics (BDS) data product. BDS products make a unique contribution to public statistics because they are longitudinal in nature, rather than being snapshots of business activity at one point in time. The BDS-CC data tables contain information not only on employment,

establishments, and firm counts, but also on job creation and destruction and establishment entry and exit, measures which capture changes from year to year. Also unique to the BDS is the length of the time series. Like the core product, BDS-CC covers the years 1978-2022, allowing users to follow business dynamics in coastal areas for over 40 years.

Many BDS-CC tables are analogous to core BDS tables, with the addition of the new coastal county indicator that divides all tables, including economy-wide, into three groups: Coastal Shoreline, Coastal Non-Shoreline, Non-Coastal. While the core BDS contains county-level statistics that provide some information about individual counties, there is no detailed industry information at the county level due to concerns about small cells that might compromise confidentiality. The BDS-CC product provides an alternative by grouping together coastal counties to create cells that are large enough to be further stratified by 3- and 4-digit NAICS industry codes. This trade-off between geographic detail and industry detail attempts to maintain some homogeneity within each geographic area while providing industry information that distinguishes between, for example, hotels and restaurants, different types of retail stores, and "high-tech" segments of the Manufacturing and Information industry sectors. Additional details about the differences between the core BDS and BDS-CC tables are included in the Data and Methodology section below.

There are already several research papers using Census data that analyze the impact of hurricanes, storms, and other natural disasters on business outcomes. For example, Basker and Miranda (2018) and Chow and Stanley (2020) look at changes in business outcomes due to hurricanes. The BDS-CC experimental data product will supplement the existing literature by facilitating some research related to coastal areas without needing to access restricted microdata.

Using the BDS-CC data, we can compare statistics between coastal areas to those that are non-coastal. Due to the longitudinal nature of the data, we can also look for historical trends in coastal areas. The patterns between various regions can be examined, and we can analyze differences in employment, job creation, and job destruction. The data can help us answer various questions such as: how does the number of establishments and firms, employment, and net job creation rate vary between coastal and non-coastal areas over time? How did Hurricane Katrina impact business dynamics in the Gulf region? Are there certain coastal areas where start-ups are more widespread? Additionally, with detailed industry information we can examine which industries are more prevalent in coastal areas and determine whether the dominant industries have changed over time. More detailed levels of geography and industry also allow us to analyze the impact of natural disasters on job creation and establishment entry and exit rate in affected regions.

This paper will proceed as follows: Section II will outline the data construction process, provide information about how coastal counties are defined, and describe the differences between BDS-CC and the core BDS data series; Section III will examine historical trends; Section IV will focus on business start-ups in coastal areas; and Section V will conclude.

II. Data and Methodology

The process of constructing the BDS-CC tables is very similar to the compilation of the core BDS tables. We begin with the Longitudinal Business Database (LBD) microdata which are compiled from the Census Bureau's Business Register (BR) and County Business Patterns (CBP) files. Each LBD record represents an establishment, defined as a business operating in a set location doing a particular type of activity. The LBD creates a unique establishment identifier over time and generates a longitudinal data series from 1976 through 2022, tracking establishments as they grow or shrink. The database is updated annually to add another year of data.

Establishments owned by a common entity are grouped together into a firm. While geography and industry are establishment characteristics, employment size and age can be measured at both the establishment and firm levels. Firm size and age are defined as total employment at all establishments owned by the firm and age of the oldest establishment belonging to the firm, respectively. Chow et al. (2021) describes the construction of the LBD in detail and provides additional information about the BDS.

The core BDS tables contain annual summary statistics for all private, non-farm establishments in the United States. These statistics include number of firms and establishments, total annual employment, openings and closings of establishments, job creation, job destruction, and firm death. Goetz and Stinson (2021) provides an overview of the BDS and highlights historic economic trends that can be seen using the BDS datasets. Further details about the concepts, key definitions, and methodology used to create the BDS are included on the BDS Methodology webpage.[6]

The BDS-CC experimental data product uses county-level establishment geography to merge the LBD with a list of coastal counties from the National Oceanic and Atmospheric Administration (NOAA). NOAA classifies counties based on whether they belong to the Coastal Watershed or not, using "NOAA coastal watersheds and U.S. Geological Survey (USGS) coastal cataloging units as delineated in the NOAA

[6] https://www.census.gov/programs-surveys/bds/documentation/methodology.html (Accessed on October 31, 2024)

Coastal Assessment Framework." The focus is on "land areas within which water flows into the ocean or Great Lakes" and expands beyond the counties that are directly adjacent to water. Counties are considered Coastal Watershed if they meet at least one of the following criteria: "(1) at a minimum, 15 percent of the county's total land area is located within a coastal watershed or (2) a portion of or an entire county accounts for at least 15 percent of a coastal USGS 8-digit cataloging unit." There are some counties on the Coastal Watershed list that are exceptions to these criteria, and these are further described in the NOAA Coastal Counties document.[7]

For the BDS-CC product, the broader category of Coastal Watershed counties is split into two groups – Coastal Shoreline (CS) and Coastal Non-Shoreline (CNS). NOAA defines Coastal Shoreline counties as those counties which are directly adjacent to the ocean, major estuaries, and the Great Lakes. The Coastal Non-Shoreline category consists of counties in the Coastal Watershed group that don't directly border the water. The remaining counties are classified as Non-Coastal (NC) counties, defined as those that have a county designation in the LBD but are not on the coastal county list. There are two additional categories of counties: Statewide (SW) and Unknown (U). These categories are assigned to records when the specific location of the establishment is unknown, or it can only be assigned a state code and not a more granular level of geography. This is consistent with the core BDS and more information about these two categories can be found on the BDS Codebook and Glossary webpage.[8] This results in each county in the LBD being placed into one of five mutually exclusive categories: CS, CNS, NC, SW, or U. Table 1 provides a list of the Coastal Shoreline and Coastal Non-Shoreline county designations for this experimental product. This coastal designation is then used to stratify statistics in the BDS-CC tables.

All coastal designations are based on 2010 county boundaries. Very few county boundaries have changed since 2010. One major exception is Connecticut, which changed from county designations to council of governments (COGs). All eight Connecticut counties are listed in NOAA's Coastal Watershed list. Therefore, when we extrapolate to the COGs, all the COGs are also included in the Coastal Watershed list. To determine the COGs that are Coastal Shoreline, we select those that directly border the water. For more information about county boundary changes, please see Appendix A.

To provide additional geographic detail to our data tables, each coastal county is further classified into one of four coastal regions: Atlantic, Great Lakes, Gulf of America, henceforth referred to

[7] https://coast.noaa.gov/data/digitalcoast/pdf/defining-coastal-counties.pdf (Accessed on February 21, 2024)
[8] https://www.census.gov/programs-surveys/bds/documentation/codebook-glossary.html (Accessed on October 31, 2024)

as Gulf, and Pacific. For the most part, all coastal counties in a state are in the same coastal region. The three exceptions are Florida (some counties in the Atlantic region and others in the Gulf region), New York (with counties in the Atlantic and Great Lakes regions), and Pennsylvania (with counties in the Atlantic and Great Lakes regions). This level of further geographic detail only exists when the coastal variable equals CS or CNS. Table 1 also shows the assigned coastal region for each coastal county. When the coastal category is NC, the coastal region variable is Non Coastal, and for the coastal categories of SW or U, the coastal region is assigned the same value.

To tabulate our data by different urban/rural categories, we put each of the counties into an urban/rural classification based on four categories: predominantly urban, mostly urban, mostly rural, and predominantly rural. These categories are consistent with those used in other BDS products (for example, the BDS-Single Unit Firms with Revenue and BDS-SBA Covid Response tables). The urban-rural categorization is based on the percentage of the total population count from the 2020 Decennial Census living in urban areas. The definitions are as follows:

- Predominantly Urban (PU) – Urban population greater than or equal to 80%
- Mostly Urban (MU) – Urban population greater than or equal to 50% and less than 80%
- Mostly Rural (MR) – Urban population greater than or equal to 20% and less than 50%
- Predominantly Rural (PR) – Urban population less than 20%

The remaining variables in the BDS-CC are analogous to those used in the core BDS: industry sector, 3-digit NAICS industry, 4-digit NAICS industry, firm age coarse, firm size coarse, initial firm size coarse, establishment age coarse, establishment size coarse, and initial establishment size coarse. Further details about these variables and their definitions can be found on the BDS Technical Documentation website.[9] Additionally, the BDS-CC follows the BDS Methodology to calculate the various employment and entity change statistics reported in the tables.[10]

There are some differences between the tables produced in the core BDS series and the BDS-CC. In addition to tables generated at the coastal region level, the BDS-CC tables contain more industry detail. Specifically, the BDS-CC provides statistics at both the coastal region level and the coastal region, urban/rural level crossed by 3-digit NAICS industry. There is also a coastal crossed by 4-digit NAICS industry table. The core BDS does not have 3- and 4-digit NAICS codes crossed by any geography below the national level. The full list of vintage 2022 BDS-CC tables produced is listed in Appendix B.

III. Historic Trends

Overall Trends and Differences Between Coastal Shoreline, Coastal Non-Shoreline, and Non-Coastal Areas

With the data in the BDS-CC tables, we can compare historic trends in coastal areas to those in non-coastal areas. Additionally, due to the longitudinal nature of the data we can see how coastal areas have changed over time.

We start by comparing employment in Coastal Watershed (CW) areas (CS plus CNS areas) and Non-Coastal (NC) areas. Figure 1 shows the time trend in employment for both groups. Overall, they follow the same pattern, increasing over time from 1978 until 2022 with decreases during macroeconomic downturn events such as the Great Recession and the COVID-19 pandemic. In 1978, there were about 38.9 million workers employed in CW areas compared to 31.1 million in NC areas. By 2022, the employment gap between the two areas had narrowed slightly with 70 million workers in CW areas and 62.3 million workers in NC areas. However, there is a larger gap between the CW and NC lines during earlier parts of the time series, which narrows around 1990. Figure 2 splits the CW group further with separate lines for CS and CNS groups. There we can see that the CS and NC areas have similar levels of employment from 1978 through 1990, while the CNS area shows a similar trend but at a much lower level. Starting in 1991, the CS and NC lines diverge with the CS line first decreasing and then growing at a lower rate than the NC line. The level of employment in CS areas never recovers to the same level as the NC areas. In 1978, NC areas had a slightly higher level of employment by about 700,000 workers. However, by 2022, that difference had grown to about 8.5 million workers.

The number of firms and establishments follow similar trends to employment. Figures 3 and 4 graph the number of firms and establishments, respectively, for the same period for CS, CNS, and NC areas. The number of firms and establishments has grown in all areas during the last 45 years, with the NC area having the highest number of both. The difference between the number of establishments in NC and CS areas narrowed in the 1980s before diverging in the 1990s and then maintaining a relatively stable gap between the two groups until 2022. The difference in the number of firms followed a similar pattern as the number of establishments in the 1980s and 1990s before narrowing again slightly to what we see in the present day. In all three major measures: firms,

establishments, and employment, we see that CS areas in aggregate had a downturn in the early 1990s and still lag behind the aggregate levels of the NC areas.

A unique feature of the BDS-CC product (and all the BDS products) is that we can look at job creation and job destruction over several years. Figure 5 shows the net job creation rate (job creation rate minus job destruction rate) for each of the three coastal groups. The peaks and valleys in this graph match with the convergence and divergence points that we saw in the coastal groups' employment graph (Figure 2) discussed above. For example, all three coastal groups saw a dip in their net job creation rate in 1991. However, the NC line decreases less than the other two and rebounds to a higher level in the following years. This coincides with the divergence point in the employment graph where the NC and CS lines split with the NC line increasing more after 1990 compared to the CS line before both lines move at a similar rate again starting in 1997.

Sectoral Employment Breakdowns in 1978 and 2022

Another feature of the BDS-CC tables is the sectoral breakdown of our statistics. We can look at what sectors are prevalent in coastal areas and whether this differs from non-coastal areas. With an additional level of geographic detail, we can also determine whether there are differences by coastal region and whether the dominant sectors in each coastal area have changed or remained constant over time. Figure 6 shows the percentage of employment in each sector in the CS group in 1978 (the first year of our series) and 2022 (the most recent year in our series). For example, in 1978, about 23% of CS employment was in the Manufacturing sector. However, by 2022, the percentage of CS employment in the Manufacturing sector dropped to about 7%. Figures 7 and 8 show the sectoral distributions for the CNS and NC groups, respectively. See Table 2 for definitions of NAICS sectors.[11] Overall, for all three groups, the distribution across sectors has been similar. In all of them, Manufacturing (31-33) was the dominant sector in 1978, but it experienced a significant decline during the last four decades. By 2022, the sector with the highest percentage of employment in all three of the groups was Health Care and Social Assistance (62). The shift in employment away from Manufacturing and into various service sectors can be seen in all three groups also. Between 1978 and 2022, a couple of differences across coastal groups include the Transportation and Warehousing (48-49) and Professional, Scientific, and Technical Services (54) sectors. The share of employment in Transportation and Warehousing (48-49) increased in CNS and NC areas relative to CS. Conversely, in

[11] This list of NAICS sectors is consistent with those used in the core BDS.

Professional, Scientific, and Technical Services (54) the CS employment share increased relative to CNS and NC areas.

Additionally, with the data available in our BDS-CC tables, we can examine how the sectoral employment levels have changed over time. In Figure 9, we show a time series of Manufacturing employment for each of the three areas. While manufacturing has declined everywhere, the timing of the decline varies across these groups. The CS and CNS areas experienced a sharp decrease in Manufacturing employment starting around 1990. This matches the decline we saw in overall employment in these areas in Figure 2 and lines up with the divergence point between the CS and NC employment series. Meanwhile in the NC counties, following a slight dip in Manufacturing employment in 1990, the overall trend increased slightly throughout the 1990s before declining sharply in the 2000s. We see a similar decrease in the CS and CNS lines during the 2000s. However, in the 2010s, the trends diverge again as Manufacturing employment increases in the NC area but remains relatively flat in the CS and CNS areas. We conclude that manufacturing has always been more prevalent in the interior of the country, and this has only increased over time. It also appears that in the aggregate, CS counties were already moving away from manufacturing activity before the entrance of China into the World Trade Organization in 2000. In contrast, NC counties in aggregate had been increasing their Manufacturing employment until 2000 and then had the largest decline in Manufacturing employment following the "China-shock."

The Impact of Hurricane Katrina on the Gulf Region

Since we have additional geographic detail for the CS and CNS areas, we can use our data to analyze what happens in certain areas following a natural disaster that would have a strong impact on coastal areas, such as a hurricane. Further, with our coastal groups crossed by coastal region and sector table, we can examine if certain industries are more affected by these events. Figure 10 shows a time series from 1990 through 2022 of the job destruction rates for the Gulf coastal region for the Accommodation and Food Services sector (72) for the CS, CNS, and NC groups. As explained previously in the Data and Methodology section, note that the NC line represents all non-coastal areas nationwide, not just in the Gulf region. From the graph, we see an increase in the job destruction rate in the CS area that coincides with when Hurricane Katrina hit the Gulf region in late 2005. Because our employment numbers are based on workers employed in the pay period that includes March 12, we first see the effect of Hurricane Katrina in 2006 when the job destruction rate reaches 20.7 percent in the CS area. For comparison, the Accommodation and Food Services sector

job destruction rate for the Gulf CNS group is 15.4 percent in 2006 and for the NC group it is 14.7 percent. In addition to the higher job destruction rate in the CS area, the job destruction rate increases from 2005 to 2006 for the CS group. This contrasts with the decrease in the job destruction rate in the CNS and NC groups during the same period. This indicates that those who work in counties that directly border the water were more negatively impacted in terms of job destruction by the hurricane than those who worked in counties that were close to but not directly touching the water.

We can also look at establishment exit rates during this time to determine whether businesses were closing completely or only reducing their workforce. As shown in Figure 11, the establishment exit rates for the CS and CNS groups are similar during most of the times series. However, when Hurricane Katrina hits, the CS line spikes relative to the CNS line. We can also compare the establishment exit rate for the Accommodation and Food Services sector with other sectors such as Retail Trade (44-45) to determine if one sector was more affected by Hurricane Katrina. As shown in Figure 12, which presents an analogous establishment exit rate graph to Figure 11 but for the Retail Trade sector, there is a similar spike in this sector when Hurricane Katrina hit. Again, the CNS line is much lower and more similar to the NC line during this time period.

Finally, we consider how job destruction rates and establishment exit rates in the Hurricane Katrina aftermath (2006) compare to the COVID-19 pandemic time period (2020-2022) for the Gulf region. As previously mentioned, in Figure 10 the Accommodation and Food Services sector job destruction rate for the Gulf CS region was 20.7 percent in 2006. From that same figure, during the COVID-19 pandemic in 2021, the job destruction rate was even higher at 23.4 percent. Similarly, in Figure 11 there is a spike in the establishment exit rate in 2021, but it is much smaller than the one in 2006 (9.8 percent in 2021 vs. 14.3 percent in 2006) and the CS line is much closer to the CNS line. One potential explanation for the lower establishment exit rate during the COVID-19 pandemic relative to Hurricane Katrina is that in 2020 and 2021 many businesses closed only temporarily. While they shed jobs during that period, they did not shut down long enough to be flagged as an exit in the BDS data. In contrast, Hurricane Katrina did more physical damage to buildings and infrastructure, which may have caused longer period of inactivity as businesses struggled to rebuild and reopen or opted to permanently close, leading to a larger increase in measured exits.[12] An

[12] The BDS identifies exits as businesses that had positive employment in the pay period that includes March 12th of the prior year but has zero employment in the pay period that includes March 12th of the current year. Thus, businesses that were closed briefly in late March/April of 2020 but re-opened by March 2021 would not be

additional factor that may have helped businesses stay open during the COVID-19 pandemic was government assistance through the Paycheck Protection Program (PPP) or COVID Economic Injury and Disaster Loans (COVID-EIDL). Another BDS experimental product, BDS-SBA Covid Response, examines the impact of these programs (see Beem and Stinson (2025) for details).

IV. Business Start-Ups in Coastal Areas

We next examine trends in entrepreneurship in coastal counties. Because our underlying data track firms with employees over time, we can measure how many new firms are born each year, where a firm birth is defined as hiring at least one employee for the first time. We assign firms an age of zero in their first year of existence as employers and refer to them as start-ups. As shown in Figure 13, between 1978 and 2022, CS counties tended to have a higher share of start-up firms relative to CNS and NC. However, the difference between CS and NC counties was small in the 1980s and 1990s. In the early 2000s, the gap grew slightly until the Great Recession, when the share of start-ups decreased in all three types of counties, with the most pronounced decline in CNS and NC counties. Following the Great Recession, coastal counties out-paced other counties in the recovery of the share of start-ups until the COVID-19 pandemic. Beginning in 2021, both CNS and NC counties saw significant increases in the share of start-ups, with NC counties mostly closing the gap with coastal counties. This is consistent with work by Decker and Haltiwanger (2023) which found that new business applications during the COVID years grew substantially in suburban counties relative to city centers, which are more likely to be coastal counties.

The BDS-CC tables also allow us to consider which coastal regions had the highest share of start-ups. Figure 14 combines CS and CNS groups for each region and compares the four different coastal watershed regions to the NC counties of the country. NC counties, on aggregate, have a similar share of start-ups compared to the Atlantic coastal counties, with the exception of the majority of years in the 2010s when Atlantic coastal counties out-pace the NC counties in the formation of new employer businesses. In contrast, the Gulf and Pacific regions generally have higher shares of start-ups compared to either the Atlantic coastal region counties or the NC counties, while the Great Lakes counties have much lower shares.

---

classified as exits in the BDS. For Hurricane Katrina, businesses that were open in March 2005 and then closed after the storm in August 2005 would be classified as exits if they were still closed in March 2006.

In Figure 15, we present the distribution of start-ups across industry sectors in 2022 for each group of counties – CS, CNS, and NC. Coastal counties have a higher share of start-ups in Professional, Scientific, and Technical Services (54) while CNS and NC counties have a higher share of start-ups in Construction (23), Manufacturing (31-33), and Retail (44-45). CNS counties had a particularly high share of start-ups in Transportation and Warehousing (48-49).

In Figures 16-20, we show a time series of the share of total start-ups in an area found in a particular industry sector for five different sectors. Trends in CNS areas are similar to those in NC areas, so we focus on comparisons between NC and CS groups. We begin with the Construction sector where we see that the share of start-ups in this sector in CS counties diverged from the share in NC counties in 1990 and has remained lower ever since. During the COVID-19 pandemic, the shares moved in opposite directions, with an increasing share of start-ups in Construction in NC counties and a decreasing share in CS counties. While the pandemic period has been an era of increasing numbers of start-ups, the composition of those start-ups has reflected growth of different types of economic activity in CS and NC counties.

In contrast, the share of start-ups in Retail converged between CS and NC counties by the mid-1990s and was very similar until 2019 when the long-run downward trend flattened out for NC counties but continued to fall for CS counties. The year 2021 saw an uptick in the share of start-ups that were in Retail in both types of counties, with this new level mostly sustained in 2022.

Transportation and Warehousing is another sector with strong historical differences between CS and NC counties. Start-ups in this sector were more common in NC counties. However, both types of counties saw a big jump in the share of start-ups in this sector in 2021 and 2022, with CS counties mostly closing the gap with NC counties.

Professional, Scientific, and Technical Services start-ups were more prevalent in CS than NC counties. This type of start-up was already increasing in share pre-pandemic in both types of counties, but after 2020, the share of start-ups in this sector declined in NC counties whereas it continued to rise through 2021 in CS counties. Finally, trends in the share of start-ups in Accommodation and Food Services (72) have been quite similar between the two types of counties since the early 2000s. Shares plummeted in 2021 but began to recover in 2022.

In summary, CS counties have higher shares of start-up firms, but this is not uniformly true across all coastal regions. Only the Pacific and Gulf coastal regions consistently out-perform NC counties. New employer businesses in CS counties also differ in their industry sector distribution. Start-ups are more likely to be in Professional, Scientific, and Technical Services if they are on the

coast whereas they are more likely to be in Construction and Transportation and Warehousing in NC areas. The share of start-ups that are restaurants, hotels, or retail stores is quite similar between the two types of counties.

V. Conclusion

The trends and analyses discussed in this paper are only a subset of information that can be found in the new BDS-CC data tables. These tables contain 45 years of data on employment, job creation/destruction, establishment entry/exit, and other business measures for CS, CNS, and NC areas. Additionally, there are many tables that are further stratified by variables such as detailed industry, establishment/firm age, establishment/firm size, urban/rural categories, and regional geography. A full list of published tables can be found in Appendix B. We plan to update this experimental data product every year to provide new estimates and add an additional year of data. These datasets can help us answer new research questions related to business differences in coastal areas.

Sources and Notes:
Compiled from a list of NOAA Coastal Counties (https://coast.noaa.gov/data/digitalcoast/pdf/defining-coastal-counties.pdf (Accessed February 21, 2024)) with edits to account for county boundary changes.

Table 2: List of NAICS Industry Sectors in the BDS

Name	NAICS code (2017 vintage)
Agriculture, Forestry, Fishing, and Hunting	11
Mining, Quarrying, and Oil and Gas Extraction	21
Utilities	22
Construction	23
Manufacturing	31-33
Wholesale Trade	42
Retail Trade	44-45
Transportation and Warehousing	48-49
Information	51
Finance and Insurance	52
Real Estate and Rental and Leasing	53
Professional, Scientific, and Technical Services	54
Management of Companies and Enterprises	55
Administrative and Support and Waste Management and Remediation Services	56
Educational Services	61
Health Care and Social Assistance	62
Arts, Entertainment, and Recreation	71
Accommodation and Food Services	72
Other Services	81

Appendix A: County Boundary Changes

To add NOAA coastal county definitions onto the LBD, we merge the NOAA coastal county list onto the LBD using the combination of the bds_st and bds_cty variables. For more information on these geography variables, see Chow, et al. (2021). NOAA's coastal counties list is based on 2010 county boundaries and there have been few changes to the county list since then. There were some changes made to the original county list to reflect updated geography in the LBD and core BDS.

One place that experienced major modifications, which was already described in the Data and Methodology section above, is Connecticut, which changed from county designations to council of governments (COGs). All eight Connecticut counties are listed in NOAA's Coastal Watershed list. Therefore, when we extrapolate to the COGs, all of the COGs are also included in the Coastal Watershed list. To determine the COGs that are Coastal Shoreline, we select those that directly border the water.

There are a few additional changes to counties in Alaska. Prior to 2015, the Kusilvak Census Area (state FIPS code 02-158) was known as Wade Hampton and had a state FIPS code of 02-270. The Wade Hampton Census Area (02-270) is included on the NOAA list of coastal counties (Coastal Shoreline). To align the NOAA list with the updated name/code of the county and the LBD data, we change the state FIPS code for Wade Hampton from 02-270 to 02-158 and update the name on our list. In 2019, the Valdez-Cordova Census Area (02-261) was split into two counties: Chugach (02-063) and Copper River (02-066). The original county, 02-261, was included on the NOAA coastal county list as Coastal Shoreline. To classify the two new counties, the one that directly borders the water, Chugach (02-063), is grouped in Coastal Shoreline and the other one, Copper River (02-066) which does not have a water border, is classified as Coastal Non-Shoreline. In addition to these changes, there are several historical Alaskan counties that previously existed but no longer exist either due to the older counties splitting or county consolidation. Due to the existence of these counties in the LBD data, we need to give them each a coastal group and urban/rural designation for our tabulations to be complete. To assign these counties a coastal group and urban/rural category, we use information from the older counties and their proximity to the Pacific Ocean.
