The research program of the Center for Economic Studies (CES) produces a wide range of economic analyses to improve the statistical programs of the U.S. Census Bureau. Many of these analyses take the form of CES research papers. The papers have not undergone the review accorded Census Bureau publications and no endorsement should be inferred. Any opinions and conclusions expressed herein are those of the author(s) and do not represent the views of the U.S. Census Bureau. All results have been reviewed to ensure that no confidential information is disclosed. Republication in whole or part must be cleared with the authors.

Papers in the series are posted on www.census.gov/library/working-papers/series/ces-wp.html. For information about the series, contact Danielle H. Sandler, Editor, Discussion Papers, U.S. Census Bureau, Center for Economic Studies, 4600 Silver Hill Road, Washington, DC 20233, CES.Working.Papers@census.gov.

Abstract

Drawing on American Community Survey data, this study examines how whites' relative socioeconomic standing vis-à-vis nonwhite neighbors affects the association between minority presence and white out-mobility. Moving beyond the racial preferences versus racial proxy debate, we integrate group competition and contact theories with status theory to conceptualize "racial status" as whites' first-order income rank relative to the subgroup status of Black, Hispanic, and Asian residents at the census tract level. Multilevel linear probability models show that whites lacking advantaged status are generally more likely to move. However, the positive association between Black or Asian concentration and white departure is weaker among status-disadvantaged whites, while the negative association with Hispanic concentration is stronger. These patterns lend greater support to contact theory than to group competition theory. By foregrounding relative status, the study demonstrates that racial and socioeconomic mechanisms are intertwined in shaping white residential mobility.

This research was performed at a Federal Statistical Research Data Center under FSRDC Project Number 1994 (CBDRB-FY22-P1994-R9688). This research uses data from the Census Bureau's Longitudinal Employer Household Dynamics Program, which was partially supported by the following National Science Foundation Grants SES-9978093, SES-0339191 and ITR-0427889; National Institute on Aging Grant AG018854; and grants from the Alfred P. Sloan Foundation.

1. Introduction

It is widely indicated that whites tend to leave communities where racial/ethnic out-groups are sizable, and two perspectives are broadly used to account for that relationship (Crowder 2000; Kye 2018). On the one hand, based on the perspective of racial preferences, whites' notable mobility tendency primarily springs from the non-white presence per se; on the other hand, according to the racial proxy perspective, the apparent mobility propensity for whites is mainly derived from the perceived to be related undesirable neighborhood socioeconomic characteristics and quality (Crowder 2000; Frey 1979; Harris 2001). Moreover, those two mechanisms usually function independently, leading to the debate over whether racial or socioeconomic conditions play a more crucial role in setting white departure in motion (Lewis, Emerson, and Klineberg 2001).

Once the notion of group position or group status is introduced and its racial aspect is accentuated, racial implications of non-white concentration are not distinguishable from the socioeconomic ones, however. Indeed, for white residents, the presence of racial/ethnic out-group communities is associated with their relative standings in the local racial hierarchy, either real or perceived (Blalock 1967; Blumer 1958; Olzak 1992). As the socioeconomically or culturally dominated group, status loss of whites may occur when the minority share in a community is conspicuous, or minority socioeconomic status is more advantaged than white inhabitants, thereby lowering their residential satisfaction and resulting in negative attitudes toward the out-group neighbors as well as the increased relocation tendencies. Thus, the existence of non-white communities is not simply race-orientated as the racial preferences perspective posits but also status-ridden. Additionally, for whites, the aggregate socioeconomic attributes of the non-white neighbors stand for not merely the unpreferred community's socioeconomic conditions, but also

their relative standing and status along the racial axis. Therefore, on top of the exogenous community socioeconomic features postulated by the racial proxy perspective, neighborhood conditions are infused with racial/ethnic significance when the intrinsic relative standing between whites and non-whites is emphasized (Taylor and Reyes 2014). In short, racial and socioeconomic preferences are interrelated and indissoluble, and minority residency influences white out-mobility via its immediate status meanings.

In the scholarship fashioned by the perspectives of racial preferences and racial proxy, how group position or racial status in a community relates to white departure is remarkedly understudied and remained unanswered. The lack of studies gives rise to the racial versus socioeconomic preferences debate which is primarily built upon the postulation that those mechanisms are at play in isolation. This is no longer the case as long as incorporating the notion of relative socioeconomic positions between white residents and non-white neighbors in the discussion. This study contributes to the literature by foregrounding the status feature pertaining to the non-white presence in explaining white out-mobility.

Group competition theory and contact theory provide a theoretical foundation to integrate the idea of racial statuses between white and non-white residents and its interplay with community racial/ethnic compositions into the white flight literature (Fiel 2015). More detailed, concentrating on the underlying mechanisms of socioeconomic standing, group competition and contact theories cast contrary speculations on how racial statuses between whites and their racial/ethnic out-groups moderate the relationship between minority presence and the views of whites toward non-whites as well as on the consequent residential mobility (Schlueter and Scheepers 2010). In a nutshell, according to group competition theory, white inhabitants are increasingly likely to hold negative attitudes toward non-whites when their racial status is inferior to the out-group neighbors, either

due to the latter's apparent population or the comparatively advantaged socioeconomic features. However, based on contact theory, in the situation above, the less negative views among whites are expected to arise because of the frequent interaction and mutual understanding opportunities (Taylor 1998; Taylor and Reyes 2014).

Building on group competition and contact theories, this article sets out to investigate how the relationship between non-white presence and white out-mobility varies with the racial status of white residents in a community. Specifically, using data from the American Community Survey (ACS), the current work delves into how the association between minority compositions, including black, Hispanic, and Asian, and the departure of white residents is contingent on the latter's socioeconomic status relative to the out-group neighbors. Compared to previous studies which exclusively rely on non-white compositions or the average socioeconomic features of local racial/ethnic communities to measure racial status, this study gauges relative socioeconomic standing by utilizing the indicators in status theory proposed by Jasso (2001). Thus, this paper elaborates on group competition/contact theories through applying them to the white out-mobility thesis as well as offering more sophisticated group position or racial status measures. More importantly, by highlighting the status implications intrinsic to minority residency, it advances the white departure literature by amending the racial preferences vs. socioeconomic preferences debate.

2. Racial Preferences and Racial Proxy Hypotheses

The scholarship has extensively revealed the positive relationship between non-white residency and the likelihood of white out-mobility. Focusing on residential mobility, for instance,

South and Crowder (1998) indicated the remarkable propensity of whites to move out of predominantly black or racially mixed neighborhoods. Crowder (2000) further pointed out that individual white householders are likely to leave a community where minority residents become populated. The salient effects of non-white group size on white out-migration persist even when individual and neighborhood characteristics are held constant, specifying the significant ingredients of neighborhood racial/ethnic conditions in accounting for white departure (Crowder 2000). Adopting the aggregate-level approach, Kye (2018) also showed the increasing out-mobility rate of whites from middle-class neighborhoods as the compositions of minority groups are on the rise.

Racial preferences and racial proxy perspectives are the two oft-cited hypotheses to shed light on the mechanisms underpinning the positive relationship between non-white presence and white out-mobility. Based on the racial preferences thesis, neighborhood racial/ethnic conditions per se are inherent in white residential disposition. On the one hand, due to the inclination to reside with the neighbors sharing the same demographic backgrounds, i.e., in-group preferences, whites tend to move away from a community where the racial/ethnic makeup is heterogenous (Hall and Crowder 2014; Pais, South, and Crowder 2009; Pais et al. 2009; Schelling 1971). Besides, whites are also likely to move into a neighborhood with a predominant share of their own racial group (Bader and Krysan 2015; Clark 1992; Crowder et al. 2012). On the other hand, white out-mobility is ascribed to the avoidance of non-white inhabitants (Emerson, Chai, and Yancey 2001; Farrell and Lee 2011; Krysan and Bader 2007; Quillian 2002), suggesting the role of out-group preferences, racial stereotypes, or racial prejudices in shaping white flight and the subsequent pattern of racial segregation (Bobo and Zubrinsky 1996; Charles 2003; Farley et al. 1994; Galster 1990; Krysan 2002; Zubrinsky and Bobo 1996; Massey and Denton 1993). Regardless of in-group

or out-group preferences, a community's racial instead of socioeconomic features lay at heart in the racial preferences perspective and white flight thesis.

In addition to racial preferences, the impact of living in a community with integrated racial/ethnic makeup on white out-mobility also operates through the perceived concomitant neighborhood characteristics with minority residency (Ellen 2000; Farrell and Lee 2011; Frey 1979; Harris 1999, 2001). As indicated by the racial proxy hypothesis, the observed positive relationship between non-white concentration and white departure is primarily rooted in neighborhood socioeconomic conditions (Harris 1999). Specifically, the noteworthy propensity of white inhabitants to leave a minority populated community results by and large from the avoidance of poverty, crime, deterioration in residential conditions, low school quality, or other nonracial problems (Harris 2001), viz., the "race-based neighborhood projection hypothesis" characterized by not present racial/ethnic composition but future neighborhood conditions (Ellen 2000). Hence, according to the racial proxy hypothesis, neighborhood socioeconomic features and quality play a nontrivial part in mediating the effects of racial makeup on white out-mobility. The associations between out-group compositions and the likelihood of white departure are expected to diminish significantly insofar as taking community socioeconomic features into account.

What racial or socioeconomic conditions of a neighborhood are more imperative in triggering white departure and the consequent residential segregation has been constantly debated in the scholarship (Emerson et al. 2001; Frey 1979; Harris 1999, 2001; Krysan and Bader 2007; Lewis et al. 2011). Crowder (2000), for instance, has shown that, controlling for individual and community socioeconomic characteristics, the positive relationship between the share of minority residents and white out-mobility endured, providing virtually little evidence for the racial proxy and socioeconomic preferences but racial preferences hypothesis (Crowder et al. 2011; Hall and

Crowder 2014). A study conducted by Krysan and Bader (2007) also put that, net of neighborhood socioeconomic characteristics, whites were notably unlikely to consider moving into a community with a majority of blacks, indicating the relatively crucial role of racial preferences instead of neighborhood quality in shaping the residential mobility of whites. Using the aggregate-level approach, Kye (2018) reported the notable pattern of white exodus – the positive relationship between non-white presence and the loss of white population independent of neighborhood socioeconomic conditions, lending support for racial preferences but not socioeconomic preferences in motivating white departure. Concerning residential satisfaction, as Swaroop and Krysan (2011) found, whites were prone to be less satisfied when having sizeable non-white neighbors, and only a modest part of the association was attributed to neighborhood socioeconomic characteristics.

In comparison, as shown by Harris (2001), the positive relationship between black concentration and residential satisfaction of whites was substantially mediated by neighborhood quality, providing more evidence for the racial proxy than the racial preferences hypothesis. With respect to residential mobility, Ellen (2000) has shown that, in congruence with the "race-based neighborhood projection hypothesis," whites tended to be more concerned about future neighborhood conditions than immediate racial composition. Nevertheless, as indicated, since the preconceptions about future neighborhood conditions were also race-related, racial/ethnic factors remained non-negligible in accounting for residential mobility processes (Ellen 2000). As a result, racially- and nonracially-linked attributes alike play crucial roles in explaining residential mobility among whites, particularly destination choice (Frey 1979).

Together, a long line of studies has juxtaposed the racial preferences and racial proxy hypotheses by comparing the effects of community racial and socioeconomic characteristics on

white out-mobility. Nonetheless, the presence of racial/ethnic out-groups in that research is overwhelmingly status irrelevant or status neutral. This is not the case, however. Given that the existence of out-group neighbors is intrinsic to the evaluation of relative status, whites may experience status loss – real or perceived – when the size of non-white residents is conspicuous. As such, on the one hand, the implications of non-white residency are not simply racial and could be distinguished from the socioeconomic status meanings as the racial preferences thesis postulates. On the other, the impact of the out-group residency on white departure does not merely operate via the concurrent neighborhood socioeconomic conditions and community quality exogenous to minority presence as posited by the racial proxy hypothesis. Instead, the existence of non-white residents is expected to exert an influence through the inherent status-related mechanisms. As this study argues, racial and socioeconomic preferences are not two distinct but intertwined mechanisms underlying the relationship between minority concentration and white out-mobility.

3. Group Competition and Contact Theories

Group competition theory and contact theory used to account for racial attitudes and segregation provide the theoretical basis to bridge the notion of racial status and the white flight literature. According to group competition or group threat theory, whites are more likely to experience status losses or threats – objectively or subjectively – when the size of racial/ethnic out-groups elevates, or as socioeconomic standing becomes less advantaged or inferior to their non-white neighbors (Blumer 1958; Blalock 1967; Fiel 2015; Taylor and Reyes 2014; Olzak 1992). Because of the heightened competition over scarce resources such as privilege or status, whites are prone to hold negative racial attitudes as their status is threatened by their increasingly less advantaged or even disadvantaged relative positions compared to the out-group communities in

the neighborhood (Quillian 1996; Schlueter and Scheepers 2010; Taylor 1998). Thus, a considerable likelihood of white out-mobility arises when status rivalries between whites and non-whites are intense (Fiel 2015) or upon white residents no longer enjoy the favorable relative status in a community. As a result, group competition theory suggests a negative relationship between the racial status of whites – characterized by the degree of concentration or local socioeconomic status of non-white communities – and their tendency to move out of a neighborhood.

Alternatively, based on contact theory, a salient or high-status non-white community may associate white departure in a reverse way. Specifically, as posited by contact theory, the prevalence of non-white residency substantially enables white inhabitants to interact with their racial/ethnic out-group neighbors frequently. Given interracial/interethnic propinquity and the consequent narrowing social distance as well as the improving mutual understanding, whites are less instead of more prone to hold negative views toward their non-white fellows in the community. However, as suggested, intergroup contacts that are beneficial to lowering racial prejudices may not occur until relative socioeconomic standing between white and not-white inhabitants are close or equitable. (Allport 1954; Pettigrew 1998; Pettigrew and Tropp 2006; Taylor and Reyes 2014), or even the status of the latter is more advantaged (Jackman and Crane 1986; Oliver and Wong 2003). In other words, contacts do not necessarily give rise to a diminish of negative racial attitudes among whites if the socioeconomic positions of non-white communities are underprivileged. Accordingly, contrary to the prediction from group competition theory, from the contact perspective, whites are less rather than more likely to leave a neighborhood where sizeable and high-status minority communities exist.

Prior studies grounded on the two theories have generally measured interracial/interethnic competitions or contacts by the size or contextual socioeconomic status of local non-white

communities. For instance, Taylor (1998) has shown that the concentration of blacks in the community significantly and positively relates to the tendency of holding negative racial views among whites. Besides, local black proportions also account for a substantial part of regional differences in the views about blacks between the South and non-South. In contrast, the relationship between Hispanic or Asian composition and whites' negativity toward the two racial/ethnic out-groups is modest (Taylor 1998). Likewise, by highlighting a "historically and culturally rooted racial/ethnic hierarchy," the positive relationship between the size of black but not Hispanic or Asian inhabitants and prejudice among whites against the corresponding minority group has been reported in the study by Dixon (2006).

However, as Dixon (2006) puts it, anti-black prejudice among whites tends to become less stark insofar as they are more familiar with their black neighbors. Focusing on the case of the Netherlands, Schlueter and Scheepers (2010) also find that the percentage of immigrant population at the municipality-level not only positively relates to anti-immigrant attitudes among Dutch citizens through the perceived immigrant group size and group threat. A high concentration of immigrant residents also encourages intergroup contacts and alleviates the perceived threat and anti-immigrant dispositions, providing credence for both group competition and contact theories (Schlueter and Scheepers 2010).

Moreover, concentrating on the black residency, Taylor and Reyes (2014) have indicated the nuanced role of aggregate socioeconomic status of local racial/ethnic out-group communities in shaping racial attitudes among whites. As stated, although the views among white residents toward blacks tend to be more positive as the level of education of black communities is high, the relationship only appears in a few dimensions of racial attitudes measures. Negative racial views among whites, by contrast, have been generally reported when the local black community is

economically deprived. In other words, when contextual black socioeconomic status in the economic aspect is less advantaged, whites are more likely to hold negative instead of positive racial views, lending support for contact theory rather than group competition theory (Taylor and Reyes 2014).

Overall, group competition and contact theories postulate a pair of competing hypotheses in connecting minority compositions or aggregate socioeconomic features and racial attitudes among whites by stressing the dynamics of relative standings between white and the racial/ethnic out-groups. Accordingly, how non-white residency relates to whites' attitudes toward minorities substantially hinges on racial status – real or perceived – between whites and non-whites in a community. Specifically, based on group competition theory, due to the intensified status competition or threats, the positive relationships between non-white residency and negative racial views among whites as well as the subsequent relocation mobility are expected to be more salient when the relative socioeconomic standing of whites is inferior to their out-group neighbors. On the contrary, according to contact theory, given the frequent between-group interactions and mutual understandings, the trends between non-white shares and whites' negative racial attitudes as well as out-mobility are likely to be less apparent or even downhill when relative socioeconomic positions of non-white communities are equal to or more advantaged than white inhabitants.

4. Conceptual Framework and Hypotheses

Building on group competition and contact theories, this study examines the relationship between minority composition and white out-mobility with particular attention paid to the moderating role of relative socioeconomic standing of whites in comparison to racial/ethnic out-group communities – including black, Hispanic, and Asian – in a neighborhood. Put differently,

this current work investigates whether and how the impact of non-white shares on white departure varies by white residents with different racial statuses regarding their socioeconomic positions relative to their minority neighbors in a community. Rather than characterizing the relative standing of white as average socioeconomic statuses of local white or non-white communities, or more roughly, racial/ethnic out-group compositions (e.g., Schlueter and Scheepers 2010; Taylor and Reyes 2014), this study assess the notion of racial status by contrasting the relative position of individual white residents in the local socioeconomic distribution with their non-white neighbors as the reference community.

This study gauges the relative socioeconomic position of whites by applying the indicators in status theory proposed by Jasso (2001, 2008). In general, status theory provides parsimonious measurements in evaluating the relative socioeconomic standing of each category in a nominal variable, such as race/ethnicity or gender, as well as status gaps between each subgroup pair of that variable nominal. Based on status theory, two kinds of status exist: (1) the status originated in the relative rank position in the distribution of a status-related attribute such as income or wealth – named the first-order status (S1) or personal status, and (2) the status derived from the summarized first-order status of each category of a nominal characteristic – termed the second-order status (S2) or subgroup status. Subgroup statuses further bring about the gaps between any pair of categories of a nominal characteristic, denoted as the second-order status gap (S2 gap) (Jasso 2001).

Grounded on status theory, this study defines the status of whites relative to non-white communities by contrasting the first-order status of individual white residents with the second-order status of the non-white neighbors. Take the relative status between whites and blacks, for instance. A white's status relative to the black neighbors is derived from juxtaposing his or her

personal status, i.e., S1, and the subgroup status, namely, S2, of blacks. Thus, the whites with a higher personal status than the subgroup status of the black community are referred to as the group having advantaged racial status. On the contrary, when white residents with personal status which is equal to or lower than the subgroup group status of blacks, they are categorized into the group without advantaged racial status. The same operationalization is applied to the white-Hispanic and white-Asian racial statuses. As a result, the current work not only directly assesses the racial status of white inhabitants in comparison to the socioeconomic standing of non-white communities. It also captures the heterogeneity of white residents vis-à-vis their relative position in a community.

Two hypotheses are drawn. According to the group competition perspective, compared to their white peers having relative status superior to the out-group communities, the positive relationship between white departure and non-white share – blacks, Hispanic, or Asian – in a community is more apparent for the white inhabitants whose racial status is not advantaged than the minority neighbors (Hypothesis 1). Based on contact theory, relative to those having advantaged racial status, the relationship between white out-mobility and non-white compositions is less noticeable for the whites whose personal status is not more favorable in relation to their out-group neighbors (Hypothesis 2).

5. Data and Methods

This study relies on restricted-use data from the 2014–2019 American Community Survey (ACS) 1-year estimates to investigate how the relationship between non-white compositions and white out-mobility hinges on the racial status of white residents. The ACS is a nationally representative survey conducted by the U.S. Census Bureau on a monthly basis and pooled across

a calendar year. In 2010, the ACS replaced the census long-form as the primary source of social and economic data for collecting population and housing characteristics in the U.S. Thus, it offers information on demographic, social, economic, and housing characteristics, including geographic mobility for households and individuals living in the 50 states and the District of Columbia.

In general, the ACS has an annual sample size of around 3.5 million addresses, providing a 1-in-100 national random sample of the U.S. population. This study uses the most recent ACS data before the COVID-19 pandemic. The analytical sample is limited to white residents who were household heads, who resided in the metropolitan areas, and who were at least 25 years old in 2018. By doing such, this study largely excludes the respondents who moved with families and those enrolled in schools. Besides, given that geographic mobility is a function of distance, the following analyses concentrate on the households whose current residence or previous residence one year ago were in the contiguous U.S.

The definition of a neighborhood is crucial in representing community contexts. As Firebaugh and Schroeder (2009) indicate, it is likely to be subjected to the issue of lack of validity by measuring neighborhood or community status from large geographic units such as states or counties. Besides, as Brodeur and Flèche (2019) discuss, assessing the socioeconomic features of the neighbors – incomes in their case – from a relatively large geographic scale is challenging to control for the variables confounding the focused effects. Accordingly, this current study defines neighborhoods as census tracts to cope with the potential measurement issues. Despite the shortcomings in delineating neighborhoods (Crowder and South 2008), census tracts are more suitable for characterizing geographic mobility than the finer spatial levels such as block groups. This is because, relative to smaller areas such as block groups, individuals or households moving between census tracts are assumed to experience more substantial changes in neighborhood

environments. Examining residential mobility between census tracts is also in line with prior studies on white out-mobility (e.g., Crowder et al. 2012; Hall and Crowder 2014; Lee 2016). Regarding the number of census tracts and residents within census tracts, take the 2010 Census, for instance. There were 73,057 census tracts with approximately between 1,200 and 8,000 individuals in the U.S.

Out-mobility, the dependent variable in this study, indicates whether a white household head had resided in different census tracts since a reference point one year ago. As a dichotomous variable, it takes a value of one for white respondents who had moved out of a census tract. By contrast, a value of zero is assigned to the individuals who had lived in the same census tract over a 12-month period, including those who had lived in the same houses or lived in different houses within the same census tract. Given that geographic mobility is measured as individuals who had changed residence across census tracts since the reference point one year ago, temporal lagged covariates at the census tract level are needed, including racial/ethnic compositions and the relative status between white residents and non-white communities. Considering that the number of observations in each census tract tends to be small on the single year ACS, this study pools the five years of data before 2019, viz., the ACS 2014, 2015, 2016, 2017, and 2018, to represent the neighborhood characteristics of 2018 for enhancing the reliability of the covariates at the census tract level.

The focal explanatory variables are racial/ethnic compositions and racial statuses between white residents and non-white communities. For racial/ethnic compositions, this study concentrates on the non-white groups having substantial population shares in the U.S., i.e., black, Hispanic, and Asian. Accordingly, racial/ethnic compositions incorporated into the subsequent

analyses are lagged proportions of non-Hispanic black, Hispanic, and Asian in each of the census tracts.

A set of racial statuses between white residents and non-white communities, the other focal explanatory variables, are reckoned as follows. First, according to status theory, this study measures the first-order status ($S1$) for individual i in census tract j (Jasso 2001):

$$S1_{ij} = \ln \frac{1}{1-r_{ij}} \tag{3.1}$$

where r_{ij} refers the relative rank ranging from zero to one on family income. Thus, a higher S_{ij} indicates higher individual status within a neighborhood.

Second, this study casts the second-order status ($S2$) for white, black, Hispanic, and Asian communities by finding the corresponding median of the first-order status of each racial/ethnic category c in census tract j:

$$S2_{cj} = \left[M(S1_{ij})\right]_{cj} \tag{3.2}$$

where $S2_{cj}$ refers to the second-order status sprung from family incomes for white, black, Hispanic, or Asian communities.

Third, this study contrasts the first-order status of white residents with the second-order status of non-white communities to come up with the racial status of whites. For instance, the racial status of whites in comparison to the black community in a neighborhood is derived from contrasting the first-order status of whites to the second-order status of black if the size of black in the neighborhood is not zero. A dichotomous variable representing the racial status of white residents compared to the black neighbors is drawn. The value of one is assigned for the white residents whose first-order status is less than or equal to the second-order status of black, and the

value of zero is given for the whites with the first-order status greater than the second-order status of black. Besides, the value of zero is also attributed to the whites living in a community with no black residents. The first refers to the absence of advantaged racial status of a white than the black neighbors, and the latter denotes advantageous racial status. This measure applies to the racial status of whites compared to the Hispanic or Asian community.

Numerous covariates at the individual or neighborhood level are held constant. Control variables at the individual level include the respondent's sex (male [omitted] vs. female), age group (25-44 years old [omitted], 45-64 years old, and 65 years old), level of education (less than higher school [omitted], high school, some college, college, and graduate school), marital status (married [omitted], separated/divorced/widowed, and never married/single), presence of children under age 18 in the family (not presence [omitted] vs. presence), nativity (native-born [omitted] vs. foreign-born), the first-order status of the white respondent, and whether living in a Metropolitan Division one year ago (no [omitted] vs. yes). Covariates at the census tract level are centralized population size in logged form, the proportion of residents sharing the same level of education with the respondent, the proportions of residents who were less than 25, 25-44, 45-64, and at least 65 years old [omitted], respectively, and the second-order status of the white community. Neighborhood median family income in logged form is also incorporated into the following analyses to adjust for the effects of undesirable neighborhood conditions related to the racial proxy hypothesis.

This study employs multilevel linear probability models to cope with the hierarchical data structure: individuals nested within census tracts. State fixed effects are specified to account for the unobserved characteristics at the state level. The following analyses concentrate on the effects of non-white compositions on white out-mobility, the influence of racial status of whites, and the

interactions between non-white shares and the racial statuses of white compared to the black, Hispanic, or Asian communities.

6. Results

Table 1 reports summary statistics of dependent and explanatory variables. As for racial/ethnic compositions, one of the focused variables accounting for white out-mobility, the communities wherein white respondents live have an average of around 78.07% of inhabitants with the same race/ethnicity, followed by roughly 10.58% of Hispanics, 6.88% of blacks, and 4.46% of Asians. Besides, regarding the racial status of whites, the other key independent variable, approximately 39.47%, 35.19%, or 30.49% of white residents whose personal status is not more favorable than the subgroup status of Asian, Hispanic, or black in the community. In short, white inhabitants tend to reside with the folks sharing the same racial/ethnic background and hold advantaged socioeconomic standing compared to their out-group neighbors.

>>> Table 1 <<<

Table 2 presents the coefficients of multilevel linear probability models estimating white out-mobility tendency by community racial/ethnic shares and the racial status of whites compared to non-white residents as a whole in a neighborhood. As shown in the baseline model (Model 0), white departure propensity is significantly associated with racial/ethnic concentrations of a neighborhood, adjusted for individual-level and census tract level covariates. However, the relationship depends on the out-group exposure is black, Hispanic, or Asian.

>>> Table 2 <<<

Specifically, according to Model 0, the likelihood of relocation for whites is positively related to black or Asian composition in a community, controlling for white and other racial/ethnic out-group concentrations. That is, the higher the black ($b = .033$, $p < .01$) or Asian share ($b = .155$, $p = < .001$) in a neighborhood, the more apparent the likelihood a white resident to move out of the community. Unlike the linear relationship between white out-mobility and black share ($b = -.006$, $p > .05$) (Figure 1), Asian composition in a community is associated with the departure of white in a non-linear way ($b = -.219$, $p = < .001$). As displayed in Figure 2, when Asian concentrations are at 10th, 50th, and 90th percentiles, white residents, on average, have around 5.9%, 6.2%, and 7.3% mobility propensities, respectively.

>>> Figure 1 <<<

>>> Figure 2 <<<

Contrary to black and Asian, a negative relationship is revealed between Hispanic share in a community and white out-mobility, net of individual-level and census tract level covariates as well as black and Asian compositions in a neighborhood ($b = -.047$, $p < .001$). Additionally, the relationship is non-linear ($b = .033$, $p < .05$). The non-linear pattern is also demonstrated in Figure 3. It is worth noting that the decreasing rate indicated above is expected to soften as the Hispanic concentration in a community grows. However, nevertheless being at the 90th percentile, the absolute Hispanic composition remains low. Consequently, the flattening pattern is unable to be shown in Figure 3. To summarize, when individual and census tract characteristics are held constant, including the white concentration as in-group preferences and other racial/ethnic out-group shares, white inhabitants are more likely to leave a community where the black or Asian residency is gradually considerable, whereas the Hispanic composition is associated to white out-mobility in a negative way.

>>> Figure 3 <<<

The relationships above change modestly after including neighborhood median family income, as shown in Model 1. The positive relationship between black residency and white out-mobility becomes more apparent when neighborhood socioeconomic conditions are taken into consideration ($b = .038$, $p < .01$). In contrast, the positive relationship between the Asian share and white relocation tendency turns out to be somewhat less noticeable ($b = .146$, $p < .001$). As for the Hispanic composition, the negative relationship becomes less noticeable slightly ($b = -.041$, $p < .01$), and the non-linear relationship falls below the statistical significance threshold ($b = .030$, $p > .05$). Broadly speaking, neighborhood socioeconomic conditions in this study slightly explain or suppress the relationship between minority compositions and white out-mobility, depending on the race/ethnicity of non-white residents. Notwithstanding the incorporation of neighborhood conditions posited by the racial proxy hypothesis, the impact of minority share on the departure of white remains significant in the analyses.

Model 2 presents the effects of relative status between white residents and out-group communities on white out-mobility. As shown, whites are prone to move out of a neighborhood once their personal status is not advantaged than the subgroup status of non-white communities in the neighborhood. Specifically, compared to their in-group members with favorable relative status, whites are more likely to leave a neighborhood by around .60, 1.00, or .70 percentage points ($p < .001$) when their personal status is not superior to the black, Hispanic, or Asian community. Such patterns persist after their personal status and subgroup status are held constant (Model 3). The results align with the postulation of group competition theory: whites tend to move out of a neighborhood when their relative socioeconomic standing is not more favorable than the out-group communities.

Model 4 observes the interactions between racial/ethnic compositions and the corresponding relative statuses of whites to test the two hypotheses of this study. The results are reported as predicted probabilities to facilitate interpretation, as shown in Figures 4–6. As indicated, the relationship between out-mobility tendency and the non-white share hinges on the relative socioeconomic standing of whites in relation to their out-group neighbors.

Specifically, according to Figure 4, whites are generally increasingly likely to move out of a neighborhood when black composition rises, and this is especially the case if their relative status is more favorable than their black neighbors as a whole. In other words, the upward tendency of out-mobility as black concentration grows is more apparent if white inhabitants enjoy a more advantaged relative standing than the average black folks in a community. Such ascending pattern, in contrast, is less noticeable for whites whose relative status is not more prosperous in comparison to the black community, controlling for their individual characteristics and neighborhood socioeconomic conditions. The results are consistent with the contact theory rather than the group competition theory. Namely, the surging trend between the black composition and out-mobility likelihood is less instead of more evident for the whites whose relative socioeconomic position is not higher than the black out-group. More importantly, although white residents in the first place are more inclined to leave a community if they do not possess a more advantageous relative standing in relation to the black community, due to the less steep uptrend, their relocation propensity turns out to be indistinguishable from their more favorable in-group peers as the black share multiplies.

>>> Figure 4 <<<

As for the Hispanic share, based on Figure 5, although the out-mobility tendency for whites decreases as their Hispanic neighbors become increasingly salient, the negative relationship is

more apparent for those without privileged racial status. Put differently, the decline of relocation propensity with the swelling of the Hispanic concentration appears to be more considerable for the white residents whose relative status is not more advantaged compared to the Hispanic community. Contrastingly, the downward pattern is less evident if the relative standing of whites is superior to the average Hispanic neighbors. Considering the originally higher relocation tendency of whites with no favorable racial status than the Hispanic out-group, the results are in line with the contact theory. Thus, the negative relationship between the Hispanic composition and white departure seems to be mainly manifested by the whites whose relative position in a community is not advantaged than nearby Hispanic residents.

>>> Figure 5 <<<

In contrast to black and Hispanic, the role of the racial status of whites in comparison with the Asian community in shaping geographic mobility appears to be more ambiguous (Figure 6). In general, as indicated, white residents display a higher propensity to move out of a community when their racial status is not superior to their Asian neighbors. Additionally, whether with more advantageous relative status than the Asian community, the out-mobility tendency for whites climbs as the Asian share becomes increasingly salient. Despite that, the dissimilarity in the growth rate is discernable between whites with differential standing in relation to the Asian out-group. Compared to those holding privileged racial status, the upward relocation propensity accompanied by the growth of Asian concentration is less responsive for the whites whose racial status is not superior to the Asian community in a neighborhood. The results suggest that, while group competition between whites and Asians in the same community prevails, the contact effects due to the non-favorable racial status exist. Thus, the results are in line with contact theory. The white

residents whose relative status is not advantaged than the Asian neighbors are less reactive to the concentration of the latter compared to their privileged folks.

>>> Figure 6 <<<

By and large, the results not only show that the relationship between non-white existence and white departure is largely contingent on racial status of whites. The findings also reveal that, for white residents with non-advantaged racial status than their out-group neighbors, their out-mobility tendency along with the changes in non-white composition is less sensitive upwardly regarding black or Asian residency, or more responsive downwardly for Hispanic presence, lending support to Hypothesis 2 derived from contact theory. However, insofar as racial status effects are evidenced, and whites without relative socioeconomic standing superior to out-group folks are more likely to leave a neighborhood than their racial/ethnic in-group peers with favorable relative position, the out-mobility of whites is also driven by group competition implications. On reflection, although whether leaving a community is originally competition motivated, as non-white shares become more salient, the assuming contact mechanisms alleviate the momentum. By contrast, due to the lack of contact, white residents with an advantaged racial status than minority neighbors display a comparatively higher propensity to move out of a neighborhood as non-white compositions rise.

7. Conclusion and Discussion

This study looks into how the relative socioeconomic standings between white residents and the racial/ethnic out-group neighbors – including blacks, Hispanics, and Asians – moderate the relationship between non-white residency and white out-mobility. With the incorporation of

the relative socioeconomic standing indicator, i.e., racial status, the current work refines the conventional framework that tends to make the distinction between racial and socioeconomic preferences and consider them in isolation in accounting for the departure of white. Indeed, due to the intrinsic attribute of racial status, the presence of minority groups in a community is not merely race- or ethnicity-related as the racial preferences hypothesis asserts but also socioeconomically ridden. Besides, for white residents, the preferred neighborhood conditions are infused with not only socioeconomic meanings as claimed by the racial proxy hypothesis but also racial/ethnic significance. In short, under the notion of racial status, racial and socioeconomic preferences are interrelated and intertwined.

The investigation builds on group competition theory and contact theory in conjunction with the status measures proposed in status theory. This study finds that white inhabitants with non-advantaged relative socioeconomic standing than their non-white neighbors, including blacks, Hispanics, and Asians, are more likely to leave a community compared to the white folks possessing superior racial status. However, looking across non-white groups, the positive relationship between white departure and black or Asian composition becomes less evident, or the negative association along with Hispanic turns to be more apparent upon the relative socioeconomic standing of whites is not superior to the non-white neighbors. The results provide evidence for the hypothesis derived from contact theory. In other words, due to the assumingly increasing contact and interaction opportunities, minority residency is less likely to spur out-mobility for the whites whose socioeconomic standing is comparable to or even disadvantaged to their non-white neighbors. With the recognition of the role of racial status in explaining white departure, this study amends the racial vs. socioeconomic preferences framework and contributes to the relevant debate.

However, given that this study utilizes an indirect approach to assess contacts through the theoretically potential mechanisms underlying the growth of non-white concentration, direct measures of the interactions between different racial/ethnic groups could be raised and included in future studies. Also, because of the employment of the ACS data and consequent constraints, attitudes among whites toward racial/ethnic out-groups pivotal in group competition and contact theories are not incorporated into the current analyses. This is also the case for the in-group identity of whites, which may play a nontrivial role in shaping the perception of group competition and the intensity of out-group contacts. Thus, how these two variables interplay with racial status in fashioning white out-mobility remains to be learned.

In addition to racial status, absolute socioeconomic indicators at the aggregate level which facilitate or impede contacts across the racial/ethnic spectrum in a neighborhood are essential ingredients in moderating the effects of minority compositions on white departure. As suggested by Taylor and Mateyka (2011), because of the potential institutional and macrosocial settings on top of micro face-to-face interactions, contextual education of the white community in a neighborhood notably molds racial attitudes among well-educated and poorly-educated whites alike. Besides, white inhabitants tend also to possess more positive racial views toward minorities, blacks in that case, when residing in localities where the black community is composed of a high degree of college graduates (Taylor and Reyes 2014).

Moreover, for white residents, the status implications derived from non-white presence are expected to directly or indirectly differ by the racial/ethnic out-groups they co-reside. In other words, the extent to which whites experience competition – perceived or real – or involve in out-group interaction opportunities is contingent on the race/ethnicity of the neighbors. Such racial/ethnic dependence, on the one hand, is likely to be rooted in the historically and culturally

rooted racial/ethnic hierarchy in the U.S. that associates with and systematically fashions the perception of threats and racial attitudes among whites toward particular out-groups (Dixon 2006). On the other, the status implications between whites and a specific non-white community are also associated with the presence of other racial/ethnic groups. To illustrate, according to the buffering hypothesis, immigrant groups such as Hispanics or Asians may function as a social and spatial buffer that facilitates the co-residence between whites and blacks (Kye and Halpern-Manners 2019). Thus, how the racial/ethnic hierarchy perspective or/and the buffering hypothesis that frames the effects of the relative status of whites on white out-mobility is worth further investigation.

Besides the locality wherein whites live, community features in the adjacent areas condition white out-mobility as well, providing the possibility to examine the white flight thesis with the spatial approach. For instance, Crowder and South (2008) have stated that neighborhood characteristics such as racial/ethnic compositions in extralocal areas, i.e., "areas surrounding a neighborhood of residence," influence geographic mobility. As they show, salient concentrations of minority groups in nearby neighborhoods lower the tendency of white out-mobility. Relatedly, housing availability derived from the local housing stock of an area also shapes residential mobility (Crowder et al. 2012; South and Crowder 1997). As a result, extending the notion of relative status from a neighborhood to the surrounding areas with the spatial specification is beneficial to advancing white out-mobility literature.
